and Alexander Kutkin

EVNs, 23.09.2016, Saint Petersburg

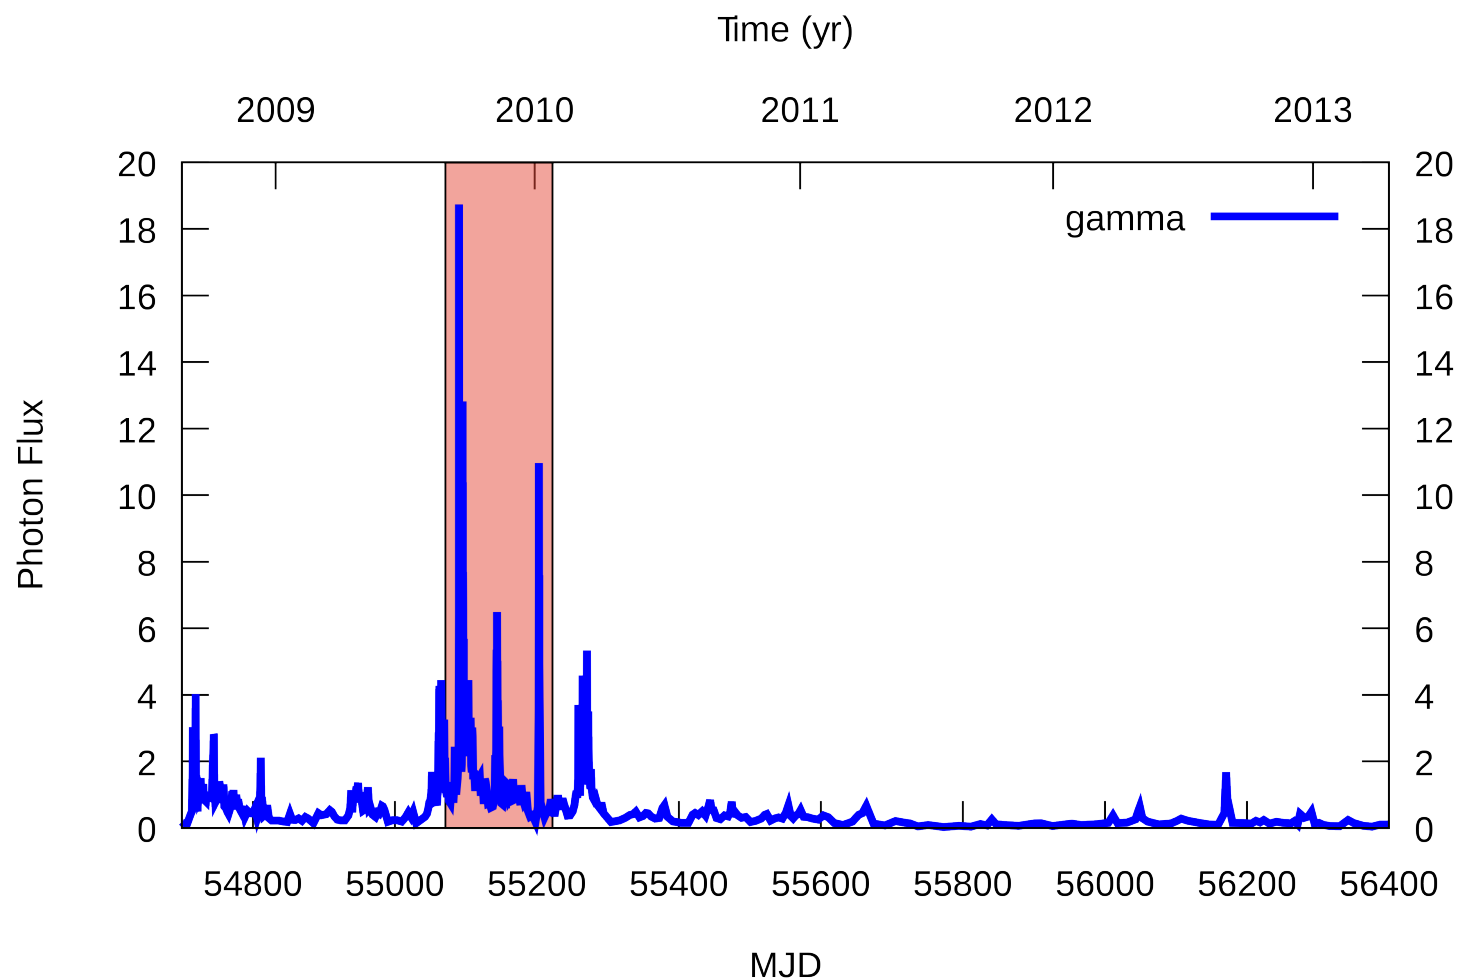

Motivation

Where does γ -ray emission originate?

Data

Fermi LAT

VLBA

**6, 4, 2,
1.3 cm
and 7 mm**

7 mm
Core

7 mm VLBI core to γ -rays distance

$$\Delta r_{R-\gamma} = \frac{\beta_{app} c \Delta t_{R-\gamma}^{obs}}{(1+z) \sin \theta}$$

24 GHz – 43 GHz spectral index

Component kinematics at 7 mm

Do γ -ray flares occur in the parsec scale jet of 3C273 ?

Moments of passing the core and stationary features do not coincide with the most powerful γ -ray flare.

But can we at least associate any component with a γ -ray flare?

C4: $\mu = 0.8 \text{ mas / yr}$
 $S_{\text{max}} = 6 \text{ Jy}$

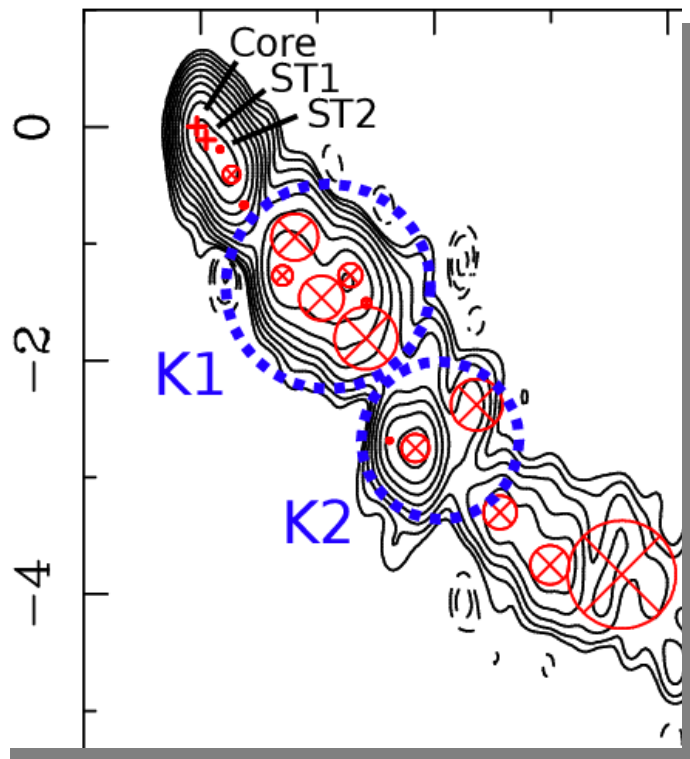

Component c4 was at the γ -ray emission site contemporaneously with the most powerful γ -ray flare

Core-shift

Conclusions

- We locate the γ -ray emission site **2-7 pc upstream** from the 7 mm core, **near to the apex** of the jet

- Radio flare is mostly caused by the raise of N_e rather than **B-field**, which is almost **constant** at the position of 7 mm core: $B_{7 \text{ mm}} = 0.3 \text{ G}$
- Component, associated with the major γ -ray flare has the **highest Flux density**

Thank you
